1

3	The present invention relates to a calibration device, and more
4	particularly to calibration device for use with a two dimensional (2D) image
5	display module having a backboard with a pattern attached thereto and a lens
6	connected to the backboard.
7	2. Description of Related Art
8	With reference to Figs. 12 and 13, a conventional two dimensional (2D)
9	image display module has a pattern (20) movably sandwiched between a
10	backboard (10) and a lens (30). A transmission device (40) having a cam (41)
11	rotatably mounted on the base plate (30) and two arms (42) pivotally connected
12	to the lens (30). Distal ends of each of the two arms (42) are connected to the cam
13	(41) such that when the cam (41) is rotated, the two arms (42) are able to pivot
14	relative to the lens (30). Because the other distal ends of the two arms (42) are
15	engaged with the pattern (20), when the two arms (42) are pivoted, the pattern
16	(20) is moved upward and downward repeatedly. The pattern (20) is thus able to
17	present different pictures based on the angle selected via the lens (30).
18	It is noted from the conventional transmission device (40) that after the
19	two arms (42) are pivoted, the pattern (20) falls back to its original position by
20	gravity. When the humidity in the air becomes dense, the movement of the
21	pattern (20) becomes sluggish and sometimes may not maintain in its original
22	space, which results in that the observer can not have a very clear image in that

- the image presenting angle between the pattern (20) and the lens (30) is mis-
- 2 aligned.
- 3 Still further, after the pattern (20) is first inserted between the lens (30)
- 4 and the backboard (10), calibration of the image presenting angle between the
- 5 pattern (20) and the lens (30) has to be done manually. That is, the operator has to
- 6 move around the pattern (20) with the lens (30) fixed or the lens (30) with the
- 7 pattern (20) moved so as to have the best image presenting angle, which is quite
- 8 troublesome and inefficient.
- 9 To overcome the shortcomings, the present invention tends to provide an
- improved calibration device for a 2D image display module to mitigate the
- 11 aforementioned problems.

12

SUMMARY OF THE INVENTION

- The primary objective of the present invention is to provide an improved
- calibration device adapted to be mounted on the 2D image display module such
- that calibration of the image presenting angle between the lens and the pattern is
- 16 easily accomplished.
- Other objects, advantages and novel features of the invention will
- become more apparent from the following detailed description when taken in
- 19 conjunction with the accompanying drawings.

20 BRIEF DESCRIPTION OF THE DRAWINGS

- Fig. 1 is a perspective view of the calibration device adapted to be
- 22 mounted on the 2D image display module;
- Fig. 2 is a schematic side view showing that the calibration device is

1 adapted to be mounted on the backboard; 2 Fig. 3 is a schematic side view showing that the calibration device is 3 adapted to be mounted on the lens; 4 Fig. 4 is a schematic view showing that the calibration device is adapted 5 to be mounted on the right side bottom corner of the lens; 6 Fig. 5 is a schematic view showing that the backboard is adjusted 7 relative to the lens via the calibration device of the present invention; 8 Fig. 6 is a schematic view showing that the calibration device is adapted to be mounted on the left side bottom corner of the lens; 9 10 Fig. 7 is a schematic view showing that the backboard is adjusted 11 relative to the lens via the calibration device of the present invention; 12 Fig. 8 is a schematic view showing that the calibration device is adapted to be mounted on the right side top corner of the lens; 13 14 Fig. 9 is a schematic view showing that the backboard is adjusted 15 relative to the lens via the calibration device of the present invention; 16 Fig. 10 is a schematic view showing that the calibration device is 17 adapted to be mounted on the left side top corner of the lens; 18 Fig. 11 is a schematic view showing that the backboard is adjusted relative to the lens via the calibration device of the present invention; 19 20 Fig. 12 is a schematic view showing a conventional transmission device 21 used in a 2D image display module; and 22 Fig. 13 is a schematic view showing that the pattern sandwiched

between the lens and the backboard is adjusted via the transmission device.

23

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

1

2 With reference to Fig. 1, it is to be noted that a two dimensional (2D) 3 image display module is essentially composed of a box (50) with a top opening, a lens (70) and a backboard (60) sandwiched between the lens (70) and a bottom 4 face defining the top opening of the box (50). A pattern (not shown) is normally 5 6 attached to a top side of the backboard (6) to face the lens (70). 7 With reference to Fig. 2, the calibration device (80) in accordance with 8 the present invention includes a securing member (81) having multiple 9 extensions (811) extending out of the backboard (60) and the lens (70) and first 10 elongated holes (82) respectively defined in opposite sides of the backboard (60) 11 and second elongated holes (83) defined in opposite sides of the lens (70). Both the first elongated holes (82) and the second elongated holes (83) correspond to 12 the extensions (811) of the securing element (81). Furthermore, a corner of the 13 14 lens (70) is securely connected to the bottom face of the top opening of the box 15 (50) via riveting resulting in that the lens (70) is pivotable relative to the box (50). 16 A cam (84) is adapted to be rotatably mounted on the bottom face defining the 17 top opening of the box (50) and extended out from a cam hole (71) adapted to be 18 defined through the lens (70). It is to be noted that each first elongated hole (82) has a dimension smaller than that of each of the second elongated hole (83). Due 19 20 to the extensions (811) extending out from both the first and second elongated 21 holes (82,83) and the cam (84) extending out from the cam hole (71) in the lens 22 (70), pivotal movement of the cam (84) allows the lens (70) to pivot as well. 23 However, when the lens (70) is pivoted, due to the extensions (811) extending

out from the first elongated holes (82) of the backboard (60), the backboard (60)

is not able to pivot along with the lens (70) but move up and down.

When the backboard (60) is forced to move up and down due to the limitation of the extensions (811) and the first elongated holes (82), relative angle between the backboard (60) and the lens (70) is changed (or adjusted). As a result, the pattern attached to a face of the backboard (60) and sandwiched between the backboard (60) and the lens (70) is able to have the best image presenting angle. A securing rod (not numbered) is provided to secure the box (50) to a surface so as to stabilize the entire 2D image display module.

With reference to Fig. 3, it is to be noted that the cam (84) is extended out of a cam hole (61) in the backboard (60). Therefore, to accomplish the same adjusting effect as that disclosed in Figs. 1 and 2, the backboard (60) has a corner riveted to the bottom face defining the top opening of the box (50) and is pivotable relative to the box (50). In this embodiment, when the cam (84) is pivoted, the pivotal movement of the backboard (60) forces the lens (70) to move up and down, which accomplishes the objective of adjusting the relative position between the lens (70) and the backboard (60) and thus an image presenting angle is adjusted.

With reference to Figs. 4 and 5, it is noted that the cam (84) is provided on the right side bottom corner of the lens (70). That is, the cam hole (71) is defined in the right side bottom corner of the lens (70) to allow the extension of the cam (84) which is rotatably adapted to be mounted on the bottom face defining the top opening of the box. Therefore, when the cam (84) is pivoted, the

- 1 upward or downward movement of the backboard (60) changes the relative
- 2 position between the backboard (60) and the lens (70), which accomplishes the
- 3 objective of adjusting the observation angle to the pattern attached to the
- 4 backboard and sandwiched between the backboard and the lens.
- With reference to Figs. 6 and 7, it is noted that the cam (84) is provided
- on the left side bottom corner of the lens (70). That is, the cam hole (71) is
- 7 defined in the left side bottom corner of the lens (70) to allow the extension of
- 8 the cam (84) which is rotatably adapted to be mounted on the bottom face
- 9 defining the top opening of the box. Therefore, when the cam (84) is pivoted, the
- upward or downward movement of the backboard (60) changes the relative
- position between the backboard (60) and the lens (70), which accomplishes the
- objective of adjusting the observation angle to the pattern attached to the
- backboard and sandwiched between the backboard and the lens.
- With reference to Figs. 8 and 9, it is noted that the cam (84) is provided
- on the right side top corner of the lens (70). That is, the cam hole (71) is defined
- in the right side top corner of the lens (70) to allow the extension of the cam (84)
- 17 which is rotatably adapted to be mounted on the bottom face defining the top
- opening of the box. Therefore, when the cam (84) is pivoted, the upward or
- downward movement of the backboard (60) changes the relative position
- between the backboard (60) and the lens (70), which accomplishes the objective
- of adjusting the observation angle to the pattern attached to the backboard and
- sandwiched between the backboard and the lens.

23

With reference to Figs. 10 and 11, it is noted that the cam (84) is

provided on the left side top corner of the lens (70). That is, the cam hole (71) is

2 defined in the left side top corner of the lens (70) to allow the extension of the

3 cam (84) which is rotatably adapted to be mounted on the bottom face defining

4 the top opening of the box. Therefore, when the cam (84) is pivoted, the upward

or downward movement of the backboard (60) changes the relative position

6 between the backboard (60) and the lens (70), which accomplishes the objective

of adjusting the observation angle to the pattern attached to the backboard and

sandwiched between the backboard and the lens.

Furthermore, the power to pivot the cam (84) may be from the operator or mechanical power, i.e. the step motor. Thus, the step motor may be programmed to adjust the relative position between the lens and the backboard to accomplish the objective of adjusting the image presenting angle.

From the foregoing description, it is noted that the pattern may be randomly placed between the lens and the backboard without worrying that the pattern might be out of focus in relation to the lens because of the provision of the calibration device of the present invention. Furthermore, the structure of the calibration device of the present invention is simple and inexpensive such that manufacturing cost is low and maintenance is easy.

It is to be understood, however, that even though numerous characteristics and advantages of the present invention have been set forth in the foregoing description, together with details of the structure and function of the invention, the disclosure is illustrative only, and changes may be made in detail, especially in matters of shape, size, and arrangement of parts within the

- 1 principles of the invention to the full extent indicated by the broad general
- 2 meaning of the terms in which the appended claims are expressed.
